DEPARTMENT OF INFORMATION TECHNOLOGY BACHELOR OF BUSINESS INFORMATION TECNNOLOGY (BBIT)

COURSE CODE: BIT 2102

COURSE TITLE: DATABASE SYSTEMS

Instructional manual for BBIT – Distance Learning

PREPARED BY: JOSHUA AGOLA

Course outline DATABASE SYSTEMS Purpose: To introduce the concept of rational database and the techniques and tools for why magnified to be able to: developing and utilizing databases in business. Objectives By the end of the course units the learner should be able to: Explain the principles underlying relational database Design and develop a practical database of Use structured query language Course Content

- Introduction to database concepts tuples, attributes
- Database models – Flat, Hierarchy, Network, Relational and object oriented.
- Database management systems, Integrity and security in database systems. Concurrency.
- Normalization 1st, 2nd and 3rd normal form.
- SQL Data manipulation, Definition and control
- Database modeling, Conceptual, logical and physical models
- Networked and distributed database systems. (partial and full)
- Data warehousing and mining.

Assessment: Examination - 70%: Coursework - 30%

Required text books

Elmasri R & Navathe, Fundamentals of database systems in business, Prentice Hall

Date C.J, An Introduction to database systems

Text books for further reading

CHAPTER ONE

INTRODUCTION TO DATABASE AND ITS ENVIRONMENT

WWW.Masomonsingi.com

Learning objectives: By the end of the chapter a student shall be able to: i. Understand the meaning of database system ii. Compare the database system and traditional file system iii. Evaluate the Database Management System iv. Differentiate types of database systems v. Understand advantages and disadvantages of database system vi. Understand the database system environment

1.1 Definition of terms

Data management: focuses on data collection, storage and retrieval, constitutes a core activity for any organization. To generate relevant information efficiently you need quick access to data (raw facts) from which the required information is produced. Efficient data management requires the use of a computer database. A database is a shared, integrated computer structure that houses a collection of:

End -user data: raw facts of interest to the user.

Meta data: The Meta data provides a description of the data characteristics and the set of relationships that link the data found within the database.

The database: resembles a very well organized electronic filing cabinet in which powerful software referred to as DBMS helps manage the cabinet's contents.

DBMS: Database Management system that enables the creation of and management of the database

- ii. A program to add a new account
- iii. A program to find the balance of an account
- A program to generate monthly statements iv.
- Any new program would be added as per the banks requirements v.

Such a typical filing /processing system has the limitation of more and more files and application programs being added to the system at any time. Such a scheme has a number of major disadvantages:

- 1. Data redundancy and inconsistency Since the files and application programs are created by different programmers over a long period of type, the files are likely to have different formats and the programs may be written in several programming languages. Moreover, the same piece of information may be duplicated in several files. This redundancy leads to higher storage and access costs. It may also lead to inconsistency i.e. the various copies of the same data may no longer agree.
- 2. **Difficulty in accessing** Suppose that one of the bank officers needs to find out the names of all customers who live within the city's 78-phone code. The officer would ask the data processing department to generate such a list. Such a request may not have been anticipated while designing the system originally and the only options available are:-
 - Extract the data manually
 - Write the necessary application; therefore do not allow the data to be accessed conveniently and efficiently

- access all the data. Since application programs are added to the system in an adhoc manner, it is difficult to enforce security constraints.
- 6. **Integrity** The data value stored in the database must satisfy certain types of consistency constraints e.g. a balance of a bank account may never fall below a prescribed value e.g. 5,000/=. These constraints are enforced in a system by adding appropriate code in the various application programs. However, when new constraints are added there is need to change the other programs to enforce.

Conclusion.

These difficulties among others have prompted the development of DBMS.

Database system

Unlike the file system with many separate and unrelated files, the Database consists of logically related data store in a single data repository. The problems inherent in file systems make using the database system very desirable and therefore, the database represents a change in the way the end user data are stored accessed and arranged.

Advantages of the Database Systems

- 1. Centralized Control Via the DBA it is possible to enforce centralized management and control of data. This means that necessary modifications, which do not affect other application changes, meet the data independence DBMS requirement.
- 2. **Reduction of redundancies -** Unnecessary duplication of data is avoided effectively reducing total amount of data required, consequently the reduction of storage space. It also eliminates extra processing necessary to trace the required data in a large mass of data. It also eliminates inconsistencies. Any redundancies that exist in the DBMS are controlled and the system ensures that his multiple copies are consistent.
- 3. Shared data In a DBMS, sharing of data under its control by a number of application programs and user is possible e.g. backups.
- 4.

- to the DBMS provide data integrity. Data integrity means that the data contained in the database is both accurate and consistent e.g. employee age must be between 28-255 on on sistent e.g. market be between 28-255 on one of the provide data integrity means that the data contained in the database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide data integrity. Data integrity means that the data contained in the database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide data integrity. Data integrity means that the data contained in the database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide data integrity. Data integrity means that the data contained in the database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the provide database is both accurate and consistent e.g. employee age must be between 28-255 on one of the pr 5. Integrity - Centralized control can also ensure that adequate checks are incorporated
- 6. Security Only authorized people must access confidential data. The DBA ensures data. Different levels of security can be implemented for various types of data or operations.
- 7. Conflict Resolution The DBA is in a position to resolve conflicting resolve conflicting requirements of various users and applications. It is by choosing the best file structure and access method to get optimum performance for the response. This could be by classifying applications into critical and less critical applications.
- 8. **Data Independence** It involves both logical and physical independence logical data independence indicates that the conceptual schemes can be changed without affecting the existing external schemes. Physical data independence indicates that the physical storage structures/devices used for storing the data would be changed without necessitating a change in the conceptual view or any of the external use.

Disadvantages of Database Systems

- 1. Cost in terms of:
 - The DBMS software
 - Purchasing or developing S/W
 - H/W
 - Workspace (disks for storage)
 - Migration (movement from tradition separate systems to an integrated one) •
- 2. Centralization Problems

You would require adequate backup incase of failure

You would require increased severity of security breaches and disruption of operation of the organization because of downtimes and failures.

3. Complexity of Backup and recovery

File System Environment

Database System Environment

The database eliminates most of the file systems' data inconsistencies, anomalies and structural dependency problems. The current generation of DBMS software stores not only the data structures in a central location but also stores the relationships between the database components. The DBMS also takes care of defining all the required access paths of the required component.

The term database system refers to an organization of components that define and regulate the collection storage, management and use of data within a database environment. The database system is composed of 5 major parts i.e.

a. Hardwareb. Software

d. Procedures

WWW.Masomonsingi.com

e. Data

c. People

 Hardware

 This identifies all the systems physical devices e.g. the composition peripherals, storage as on the systems physical devices e.g. the composition peripherals, storage as on the systems used by the computers within the database i. O.S - manages all hardware components and metal and software to run on the components and metal and software to run on the components.

 ii. The DBMS

- DB2, Ms Access etc.
- iii. Applications programs and utilities to access and manipulate data in the DBMS.

People

These are all database systems users:-

- 1. Systems administrator Oversees the database systems general operations.
- 2. Database administrator (DBA) Manages the DBMS use and ensures that the database is functioning properly. His functions include:
 - i. Scheme definition The original database scheme is created by writing a set of definitions, which are translated by DDL compiler to a set of tables that are permanently stored in the data dictionary.
 - ii. Storage structure and Access Methods Definitions By writing a set of definitions for appropriate storage structures and access methods, which are translated by the data storage and definition language compiler.
 - iii. Scheme and physical organisation modifications Modification to either the database schema or description of the physical storage organisation are accompanied by writing a set of definitions which are used by either the DDL compiler or the data storage and definition language compiler to generate modification to appropriate internal systems tables e.g. data dictionary.
 - iv. Granting authorization to data access This is so as to regulate which parts of the database users can access.
 - v. The database manager keeps integrity Constrains in a special system structure whenever an update takes place in the system.
- 3. **Database designers** These are the database architects who design the database structure.
- 4. Systems Analysts & Programmers (application programmers) They design and implement the application programs they design & create the data entry scheme, reports & procedures through which users access and manipulate the databases data.

- 5. End users These are the people who use the application programs to run the organizations daily operations. They fall in the following classes:
- MM. Masomonsingi. com i. **Sophisticated users** - These interact with the system without writing programs. They form their requests in a database query language.
 - ii. Specialized database applications that do not fit in the traditional data processing framework e.g. CAD Systems, knowledge based & expect systems.
 - iii. Application programmers: These interact with the system through the DML & applications.
 - iv. Naive Unsophisticated user who interact with the systems by invoking one of the permanent application programs that have been written previously.

Procedures

- These are instructions and rules that govern the design and use of the database system.
- They enforce standards by which business is conducted within the organisation an with customers.
- They also ensure that there is an organized way to monitor and audit both the data that enter the database and the information that is generated through the use of such data.

Data

This covers the collection for facts stored in the database and since data is the raw

material from which information is generated the determination of what data is to be

stored into the database and how the data is to be organized is a vital part of the database

- A DBMS is software used to build, maintain and control database systems. It allowed no on the storage and retrieval of data in a computer. Most DBMS(s) have several major components, which include the following 1. Data Definition Language (DDL) These arr altering the structure of the data' The structures or or or of the data' organizational technique. The DDL commands are used to create new objects, alter the structure of existing ones or completely remove objects from the system.
- 2. Data Manipulation language (DML) This is the user language interface and is used for executing and modifying the contents of the database. These commands allow access and manipulation of data for output. They include commands for adding, inserting, deleting, sorting, displaying, painting etc. These are the most frequently used commands once the database has been created.

Interactive Data Manipulation Language (DML) - DML includes a query language based on both relational calculus. It includes commands to insert tuples into, delete tuples from and modify tuples in the database.

Embedded DML - This is designed for use within general purpose programming languages such as PL/1. Cobol, Pascal, Fortran and C.

- 3. Data Control Language (DCL) These are commands used to control access to the database in response to DML commands. It acts as an interface between the DML and the OS. It provides security and control to the data.
- 4. Query Languages A query language is a formalized method of constructing queries in database system. It provides the ways in which the user interrogates the database for data without using conventional programs. For relation database, structures query languages (SQL) has emerged as the standard language. Almost all the DBMS(s) use SQL running on machines ranging from microcomputers to large main frames.
- i. View Definition The SQL DDL includes commands for specifying access rights to relations and view.
- ii. Integrity The SQL DDL includes commands for specifying integrity constraints that the data stored in the database must satisfy. Updates that violate integrity constraints as disallowed.
- iii. Transaction Control SQL includes commands for specifying the beginning and ending of transactions. Several implementations also allow explicit locking of data for concurrency control.

Basic Structure of SQL Statement

Basic structure of an SQL expression consists of 3 clauses;

- i. SELECT
- ii. FROM
- iii. WHERE

SELECT

This corresponds o a projection operation of the relational algebra. Its used to list the attributed desired in the result of a query.

WWW.Masomonsingi.com

FROM

This corresponds to a Cartesian product operation of the relational algebra. It lists the relations to be scanned in the evaluation of the expression

WHERE

Corresponds to the predicate of the relational algebra. It consist of a predicate involving attributes of the relations that appear in the **FROM** clause.

A typical SQL query will be of the form: **SELECT**

A₁,A₂, A₃,A_n

FROM

 $R_1, R_2, R_3, \dots, R_n$ **WHERE** P

A_i represents an attribute; each r a relation and P is a predicate.

Select clause

Examples (i) **SELECT** Branch name **FROM** Loan

(ii) **SELECT DISTINCT** Branch-name **FROM** Loan

The symbol * can be used to denote all attributes of a given relation (iii) SELECT * FROM Loan

STUDENT			COURSE		
<u>Code</u>	<u>Stud.id</u>	<u>Name</u>	<u>Code</u>	<u>Title</u>	
IMIS	001	Charles	IMIS	Info. Systems	
BIT	002	Mary	BIT	Bachelor of IT	
BIT	003	Maina	CIT	Cert in IT	
CIT	004	Judy	DIT	Dip in IT	

www.masomonsingi.com

Select Stud-Id, Name, Code, Title From Student, Course Where Student.Code = Course.Code

The select clause can also contain arithmetical expressions involving operations +, -, *, and operating on constants or attributes of tables e.g.

SELECTBranch_name, Loan_number, Amount*100FROMloan

Where Clause

Specifies a condition that has to be met. SQL uses the logical connectives AND, OR and NOT in the where clause. It also uses operands of logical connectives <, <=, >, >=, = and <>. It also includes a BETWEEN operations e.g.

(i) Select loan_number From loan

(ii) Select loan_number
 From loan
 Where branch_name = "River Road" and Amount Between 10,000 And 15,000.

From Clause

This specifies the source (relations), which is a Cartesian product. The SQL uses the notion relation-name. Attribute-name to avoid ambiguity in case where an attribute appears in the schemer of more that one relation e.g.

Example Select Customer_name, borrower. loan number From borrower, loan Where borrower.loan_number = loan.loan_number AND branch_name= "Moi Avenue"

SQL provides a mechanism for renaming both relations and attributes by use of the SA's clause it is of the form Old_name AS New_name. e.g. Select distinct Customer_name, Borrower. Loan -'rom Borrower, loan Vhere Borrower. Loan ND Brow **AND** Branch_name = "Koinange Street"

Ordering Display of Tuples

The "order by" clause case the tuples in the result for a query to appear in sorted order e.g.

Select distinct Customer - name **From** borrower, loan Where borrower.loan_number = loan.loan_number **And** Branch name = "University way" Order by customer name

By default the order by clause lists items in ascending order. To specify the sort order use 'desc' for descending order or 'asc' for ascending e.g.

Select * From loan Order by amount desc, loan-number desc

Aggregate Functions

W.Masomonsingi.com These are functions that take a collection (set or multi-set) of values as input and return a single value. These are

Average: Avg Minimum: Min Maximum: Max Total: Sum Count: Count

The input to sum and average must be a collection of numbers but the other operators can operate on collection of non-numeric data-types e.g. strings

Example

(i)	SELECT FROM GROUP BY	Branch name, Avg(balance) Account Branch -name
(ii)	SELECT FROM WHERE GROUP BY	Branch_name, count (distinct customer_name) Depositor, account Depositor, account-number = account - number Branch name
(ii)	SELECT FROM GROUP BY HAVING	Branch_name, Avg(balance) Account Branch_name Average (balance) > 1200

Null Values

Null values indicate absence of information about the value of an attribute. e.g. SELECT loan-number FROM loan WHERE Amount is **Null**

Assignment: look into Inner Join and Outer Join

Tuple Variables

• A tuple variable in SQL must be associated with a particular relation They are defined in the FROM clause via the use of the AS clause. e.g.

SELECT DISTINCT Customer_name, T.loan_number FROM Borrower AS T, loan AS S **WHERE** T.loan_number = S.Loan_number

Query to find the names of all branches that have assets greater than at least one branch as one branch as one branch as a set of the set of th

name is an implicitly defined tuple variable.

String Operations

- Most commonly used operation on strings is pattern matching using "LIKE".
- Two characters are used
 - Percent (%) matches any sub-string
 - Underscore (-) matches any character
- Patterns are case sensitive i.e. uppercase do not match lower case characters.

Examples

- "Mary %" matches any string beginning with "Mary" (i)
- (ii) "%ry" Matches any string containing "ry" as a sub-string e.g. very, mary, ary etc.
- "- -" Matches any string of exactly three characters. (iii)
- "---%" Matches any string of at least 3 characters. (iv)

The query to find customer names for all customers whose addresses include the substring "main" would be:-

SELECT Customer-name **FROM** Customer WHERE Customer -street LIKE "%main %"

For patterns to include special pattern characters (i.e. % and) SQL allows the specification of an escape character. The escape character is placed immediately before a special pattern character to indicate the special pattern. Character is to be treated like a normal character. The key work ESCAPE is used.

Examples.

- LIKE "ab\%cd%"ESCAPE "\" matches all strings beginning with "ab%cd"
- LIKE "ab\\cd%" ESCAPE"\" matches all strings beginning with "ab\cd"

Mismatches.

SQL allows the search for mismatches using the NOT LIKE comparison operator Set Operations.

SQL and Set SQL operations Union, Intersect and Except operate on relations and correspond to the asomorphism relational operations D, D and -, when the asomorphism of the asomorphism (i) Union To find all customers having a loan, an account or both as a SELECT Customer and

UNION (SELECT Customer_name **FROM** Borrower)

To indicate duplicates

(SELECT Customer_name FROM Depositor)

UNION ALL (SELECT Customer_name **FROM** Borrower)

(ii) The Intersection

To find customers who have both a loan and an account at the bank

(SELECT Distinct Customer_name **FROM** Depositor) **INTERSECT** (SELECT Distinct Customer_name **FROM** Borrower)

To include duplicates we use "intersect all"

(iii) The Exception

To find customers who have an account but no loan at the bank we write

(SELECT Distinct Customer_name FROM Depositor)

EXCEPT

(SELECT Customer_name FROM Borrower)

To include duplicate we use "Except all" Null Values

• The keyword is used in the predicate test.

Example

SELECT Loan_number FROM Loan WHERE Amount is NULL

• To test for the absence of a null value we use the predicate "IS NOT NULL"

WWW.Masomonsingi.com

VIEWS

Use **CREATE VIEW** command Syntax

CREATE VIEW V **AS** *<query expression>* Where query expression is a legal query expression.

Example **CREATE VIEW** Customer **AS** (**SELECT** Branch_name, Customer_name **FROM** Depositor.account) **WHERE** Depositor.Account_number, Account_account_number

The names of the attribute of a view can be specified as

CREATE VIEW Branch_total_loan(branch-name, total(loan) AS SELECT Branch_name, SUM (amount) FROM loan GROUP BY Branch_name

NB: A create view clause creates a view definition in the database which stays there until a command **DROP** View (view name) is executed.

Modification Of The Database

Involves Add, REMOVE or CHANGE of information in the database.

(i) Deletion

DELETE FROM r **WHERE** P

WHERE P

- P represents the predicate, r represent the relation.
- The statement first finds all tuples t in r which P(t) is true & then deletes them from r

www.masomonsingi.com

• Where clause can be omitted in which case all tuples in P are deleted.

Example **DELETE FROM** Loan

- Deletes all tuples from the loan relation.

To delete all loans with loan amounts between 1300 &1500

DELETE FROM loan WHERE amount BETWEEN 1300 AND 1500

To delete all accounts at city square branch

DELETE FROM account

WHERE Branch-name = "City Square"

(ii) Insertion

To insert data into a relation:-

- Specify a tuple to be inserted or
- Write a query whose result is a set of tuples to be inserted

Tuples to be inserted must be in the correct arity.

Example

INSERT INTO Account VALUES ("City Square", " Account", 6000) or INSERT INTO Account (branch-name, account-number, balance) VALUES ("City Square", "Account", 6000)

(iii) Updates

To change a value in a tuple without changing all values the **UPDATE** statement can be used.

Examples

- (i) UPDATE Account SET Balance = Balance * 1.05
- (ii) **UPDATE** Account

Update Of A View A modification is permitted through a view only if the view in question is defined in terms of one relation of the actual relational database i.e. of a logical level db Example CREATE VIEW Branch_loan AS VELECT Branch_name, loan_number ROM loan VSERT INTO T AUTT VALUES ("Moi Avenue", "Accoo8")

Schema Definition in SQL

Syntax **CREATE TABLE** r(A1D1, A2D2, ----, A_nD_n, [Integrity Constraints],

> . [Integrity - constraints]

Examples

- (i) **CREATE TABLE** Customer (Customer_name CHAR(20) NOT NULL, Customer_street CHAR(30), Customer_city CHAR(30), **PRIMARY KEY** (customer_name))
- (ii) **CREATE TABLE** Branch (Branch_name CHAR (15) NOT NULL, Branch city CHAR (30), Assets Integer, **PRIMARY KEY** (Branch name) **Check** (assets> = 0))
- (iii) **CREATE TABLE** Depositor (customer_name, CHAR(20) NOT NULL, Account_name CHAR(20) NOT NULL, **PRIMARY KEY** (Customer_name, Account_number))

The create table commands includes other integrity constraints.

• Primary key - includes a list of the attributes that constitute the primary key

- Unique includes a list of the attributes that constitute a candidate key
 Foreign key includes both a list of the attributes that constitute the foreign key & the some of the relation referenced by the foreign key.
 1.4 The three-level architecture and its purpose
 Abstraction and Data Integration

Abstraction is the simplification mechanism to hide superfluous (extra/surplus/unnecessary) details of a set of objects. It allows one to concentrate on the properties that are of interest to the application e.g. a car is an abstraction of personal transportation vehicle but does not reveal details about model, year, colour etc.

Vehicle itself is an abstraction that includes the types; car, truck, bus and lorry. Consider a non- database environment of a number of application programs as shown below:

Application 1 will contain values for the attributes employee Name and Employee. Address and this record can be described in pseudo-code as

Type Employee = record Employee.name:string Employee.address:string End

Application 2 will have:

Type Employee = record Employee.name: String Employee.soc_sec_No: Integer Employee.Adress: String Employee. Annual_salary:integer End

In a non-database environment each application is responsible for maintaining the currency of data and a change in data item.

In a database environment, data can be stored in this application and their requirement be integrated by whoever is responsible for centralized control (DBA).

The integrated version would appear as recorded containing attributes required by both applications.

The record will appear as:

Type Employee = record Employee.Name:string

Employee.soc-sec.no: Integer Employee.Address:string Employee.Address:string Employee.Annual_Salary: double End The views supported are derived from the conceptual record by using appropriate mapping. The application programs no longer require information about the store storage device types or access methods. These are absorbed to There are 3 level abstractions correspondent i. The highest level

- "external or user view"
- ii. A sum total of users view called global view a conceptual view.
- iii. Lower level which is the description of the actual method of storing the data. It is also referred to as the internal view.

www.masomonsingi.com The 3 level scheme architecture is called the ANSI/SPARC model (American National Standard Institute/Standards Planning and Requirements Committee.) It is divided into 3 levels:

- External
- Conceptual
- Internal •

The view of each level is described as a scheme, which is an outline or a plan that describes the records and relations existing in the view. It also describes the way in which entities at one level of abstraction can be mapped onto the next level. External Level (External or User view)

This is at the highest level of database abstraction where only those portions of the database of concern to the user or application programs are included.

Any number of user views may be possible, some of which may be identical. Each external view is described by means of a scheme called external scheme, which consists of a definition of the logical records and the relationships in the external view. It also contains the method of devising the objects in the external view from the objects in the conceptual view (entities, attributes and relationships).

Conceptual or Global View

Contains all database entities and the relationships among them are included and one conceptual view represents the entire database.

It is defined by the conceptual scheme. Also contains the methods of deriving the objects in the conceptual view from the object s in the internal view. It is independent of the physical presentation.

Internal View

This is the lowest level of abstraction closest to the physical storage method used. It indicated how data would be stored and describe the data structures and access methods to be used by the database. The internal schema implements it.

Internal Level

The 3 levels of architecture of a DBMS

Mapping between views

WWW.Masomonsingi.com Two mappings are required, one between external and conceptual views and another between the conceptual records to internal ones.

Data Independence

This is the immunity of users/application programs from changes in storage structure and access mechanism.

The 3 levels of abstractions along with the mappings from internal to conceptual and from conceptual to external provide 2 distinct levels of data independence i.e.:

- Logical Data Independence
- Physical Data Independence
- (i) Logical Data Independence

This indicates that the conceptual schema can be changed without affecting the existing external schema.

The mapping between the external and conceptual levels would absorb the change.

It also insulates application programs from operations such as combining two records into one or splitting an existing record into 2 or more records. The LDI is achieved by providing the external level or user view database.

The application programs or users see the database as described by the respective external view.

DBMS provided a mapping from this view to the conceptual view.

NB: The view at conceptual level of the database is the sum total of the current and anticipated views of the database.

(ii) Physical Data Independence

This indicates that the physical storage structures or devices used for storing the data can be changed without necessitating a change in the conceptual view or any of the external view. Any change is absorbed by the mapping between the conceptual and internal views.

1.5 Classification of DBMS

i. Single User database systems

www.masomomsingi.com This is a database system that supports one user at a time such that if user A is using the database, users B & C must wait until user A complete his or her database work. If a single user database runs on a personal computer it's called a desktop database.

ii. Multi-user database

This is a database that supports multiple users at the same time for relatively small number e.g. 50 users in a department the database is referred to as a workgroup database. While one, which supports many departments is called an enterprise database.

iii. Centralized Database system

This is a database system that supports a database located at a single site.

iv. Distributed database system

This is a database system that supports a database distributed across several different sites.

v. Transactional DBMS/Production DBMS

This is a database system that supports immediate response transaction e.g. sale of a product.

vi. Decision Support DBMS

It focuses primarily on the production of information required to make a tactical or strategic decision at middle and high management levels.

Chapter Review Questions

- vann. masomonsingi.com 1. List and briefly describe advantages and disadvantages of database systems.
- 2. State the components of database system environment
- 3. State and explain four types of database languages
- 4. Identify and explain the classification of DBMS

Cornolly T. \$Begg C., Database systems: a practical approach to design, implementation and management

www.masomornsingi.com

CHAPTER TWO

CONCEPTUAL DATA MODELING

2.1 The E- R Model (Entity Relationship)

It is based on a perception over a real world, which consists of a collection of basic objects called entities and relationships among this objects. An entity is an object that is distinguished from other objects via a specific set of attributes.

E-R Model Basic Concepts

The model employs the following components:

- Entity sets
- Relationship sets
- Attributes

1. Entity sets

An entity is a thing or object in the real world that is distinguishable from all other objects. It may be concrete e.g. a person or a book or it may be abstract e.g. a loan, holiday a concept etc. An entity set is a set of entities of the same type that share the same properties or attitudes e.g. a set of all persons who are customers of a bank.

Weak Entity Set

Entity set that does not have sufficient attributes to form a primary e.g. an entity set payments comprising of the attributes payment number, payment date and payment amount. Although each payment entity is distinct, payment for different loan e.g. may share the same payment number thus this entity set does not have a primate ker. Strong Entity Set This is an entity set that has a primary key E-be part of a one to many relation

2. Relationship sets

An association between two or more entities is called a relationship.

A relationship is an association amongst several entities while a relationship set is a set of relationships of the same tuple. It is a mathematical relation on n>2 possible non-distinct entity sets e.g. consider 2 entity sets, loan and branch. A relationship set loan, branch can be defined to denote association between a bank loan and the branch in which that loan is obtained.

They represent logical links between two or more entities.

WWW.Masomonsingi.com

Entity-Relationship Diagram

Components of E-R diagram

Example of relationship

Residence is an example of a relationship that can exist between the entities City and Employee; Exam is an example of a relationship that can exist between the entities Student and Course.

An instance of a relationship is an n-tuple made up of instances of entities, one for each of the entities involved.

The pair (Johanssen, Stockholm), or the pair (Peterson, Oslo), are examples of instances in the relationship Residence.

Types of Relationships

- i. One to one relationship (1:1) An entity in A is associated with utmost one entity in
- ii. B is associated with at utmost one entity in A.

iii. One to Many relationship (1:M) - An entity in A is associated with any number of entities in B while an entity in B can be associated with at most one entity in A .

iv. Many to one relationship (M:1) - An entity in A is associated with at most one entity as one of the second matrix in B and an entity in B can be associated with a number of entities in A. M^{M}

v. Many to many (M:N) - An entity in A is associated with at least one entity in B and an entity in B can be associated with a number of entities in A.

Existence Dependencies

If the existence of an entity X depends on the existence of entity Y, then X is said to be existence dependent on Y. If Y is deleted, so is X. Y is said to be the dominant entity and X is said to be subordinate entity.

Recursive Relationships Recursive relationships are also possible, that is relationships between an entity and itselfs of the second example that the relationship is not symmetric. In this case it is Note in the second example that the relationship is not symmetric. In this case it is necessary to indicate the two roles that the entity involved plays in the relationships with

Identifiers

Identifiers (or keys) consist of one or more attributes which identify uniquely instances of an entity. In many cases, an identifier is formed by one or more attributes of the entity itself: in this case we talk about an internal identifier. Sometimes, however, the attributes of an entity are not sufficient to identify its instances unambiguously and other entities are involved in the identification. Identifiers of this type are called external identifiers. An identifier for a relationship consists of identifiers for all the entities it relates. For example, the identifier for the relationship (Person-) Owns(-Car) is a combination of the Person and Car identifiers.

Schema with Identifiers

3. Attributes

These describe the elementary properties of entities or relationships. For example, Surname, Salary and Age are possible attributes of the Employee entity, while Date and Mark are possible attributes for the relationship Exam between Student and Course. An attribute associates with each instance of an entity (or relationship) a value belonging to a set known as the domain of the attribute. The domain contains the admissible values for the attribute.

They are descriptive properties or characteristics possessed by each member of an entity set.

Characteristics of Attributes

- 1. Simple and Composite attributes e.g. a customer name or first name, middle name, last name. Composite attributes are necessary if a user wishes to refer to entire attribute on some occasions and to only a component of the attributes on other occasions.
- 2. Single valued and Multi valued Attribute The social security number or ID number can only have a single value at any instance and therefore its said to be single valued. An attribute like dependent name can take several values ranging from o-n thus it is said to be multi valued.

- A null value is used when an entity does not have a value for an another e.g. dependent name.
 4. Calculated attribute The value for this type of attribute can be derived from the maximum resonance of other related attributes or entities e.g.
 i. Employment length value can be derived from the the current date.
 ii. Loans held can be a court

Composite Attributes

It is sometimes convenient to group attributes of the same entity or relationship that have closely connected meanings or uses. Such groupings are called composite attributes.

Structured constrains (Cardinalities)

These are specified for each entity participating in a relationship and describe the maximum and minimum number of relationship occurrences in which an entity occurrence can participate. Cardinalities state how many times can an entity instance participate in instances of a given relationship. In principle, a cardinality is any pair of non-negative integers (n,m) such that n≤m. or a pair of the form (n,N) where N means "any number". If minimum cardinality is 0, we say that entity participation in a relationship is optional. If minimum cardinality is 1, we say that entity participation in a relationship is mandatory. If maximum cardinality is 1, each instance of the entity is associated at most with a single instance of the relationship; if maximum cardinality is N, then each instance of the entity is associated with an arbitrary number of instances of the relationship.

Cardinality Example

Enhanced E-R Model

Specialization

WWW.Masomonsingi.com An entity set may include sub-groupings of entities that are distinct in some way from other entities in the set. This is called specialization of the entity set e.g. the entity bank account could have different types e.g.

> Credit account Checking account Savings account - interest rate Checking account - overdraft amount

Under checking account you could have type:

- i. Standard check account
- ii. Gold checking account
- iii. Senior checking account

For the standard if may be divided by number count of checks gold minimum balance and an interest payment.

Senior checking account - age limit

A specialised entity set may be specialised by one or more distinguishing features.

Aggregation

This is abstraction through which relationship are heated as higher-level entities e.g. the relationship set borrower and the entity sets customer and loan can be treated as a higher set called borrower as a whole.

Entity modeling (Diagrammatic representation) relationships

i. One to one relationship

ii. One to many relationship

iii. Many to many relationship

NB: Whenever the degree of a relationship is many to many we must decompose the mason on single on the relationship to one-to-one or one-to-many. The decomposition process will create the mean entity. Mandatory and Optional
Diptional relationships are shown in lotted line while

dotted line while mandatory relationships are shown by use of either a bar drawn across the line or a continuous line.

Optional

Mandatory

Generalizations

These represent logical links between an entity E, known as parent entity, and one or more entities E1,...,En called child entities, of which E is more general, in the sense that they are a particular case.

In this situation we say that E is a generalization of E1,...,En and that the entities E1,...,En are **specializations** of E.

Properties of Generalization

Every instance of a child entity is also an instance of the parent entity. Every property of the parent entity (attribute, identifier, relationship or other generalization) is also a property of a child entity. This property of generalizations is known as inheritance.

A generalizations A generalization is **total** if every instance of the parent entity is also an instance of one of its children, otherwise it is **partial**. A generalization is **exclusive** if every instance of the parent entity is at most an instance of one of the children, otherwise it is **overlor** The generalization Person, of Man and Woman is total (the sets of constitute 'all' the people) and exclusive (a person is cont The generalization Vehicle of Automobil-nere are other types of vehications) bicycle.

The generalization Person of Student and Employee is partial and overlapping, because there are students who are also employed.

Generalization Hierarchies

Total generalization is represented by a solid arrow. In most applications, modeling the domain involves a hierarchy of generalizations that includes several

Super classes and Subclasses

Subclass = special case = fewer entities = more properties. Example: Ales are a kind of beer. In addition to the properties (= attributes and relationships) of beers, there is a "color" attribute for tusker.

- · Assume subclasses form a tree (no multiple inheritance).
- · isa triangles indicate the subclass relation.

Multiple Inheritance

Theoretically, an E.S. could be a subclass of several other entity sets.

Chapter Review Questions

- 1. Differentiate between an attribute and entity
- 2. What is the difference between specialization and generalization

1 www.masomornsingi.com

3. Why and when do we use E-R diagram?

Cornolly T. \$Begg C., *Database systems: a practical approach to design, implementation and management*

CHAPTER THREE

CONCEPTUAL DATA MODELING

Learning objectives:

By the end of the chapter a student shall be able to:

WWW.Masomonsingi.com

- i. Understand properties of database relations
- ii. Identify candidate, primary and foreign keys
- iii. Entity integrity
- iv. Referential integrity

3.1 Properties of Relations

- Each tuple is distinct; there are no duplicate tuples.
- Order of attributes has no significance.
- Order of tuples has no significance, theoretically.

3.2 Relational Keys

Super key

 \odot

An attribute or a set of attributes, that uniquely identifies a tuple within a relation. **Candidate Key**

- \checkmark Super key (K) such that no proper subset is a super key within the relation.
- ✓ In each tuple of R, values of K uniquely identify that tuple (uniqueness).
- ✓ No proper subset of K has the uniqueness property (irreducibility

Primary Key

✓ Candidate key selected to identify tuples uniquely within relation.

Alternate Keys

 \checkmark Candidate keys that are not selected to be primary key.

Foreign Key

✓ Attribute, or set of attributes, within one relation that matches candidate key of some (possibly same) relation.

Null

- \checkmark Represents value for an attribute that is currently unknown or not applicable for tuple.
- \checkmark Deals with incomplete or exceptional data.
- W.Masomonsingi.com \checkmark Represents the absence of a value and is not the same as zero or spaces, which are values.

Entity Integrity

 \checkmark In a base relation, no attribute of a primary key can be null.

Referential Integrity

 \checkmark If foreign key exists in a relation, either foreign key value must match a candidate key value of some tuple in its home relation or foreign key value must be wholly null.

Enterprise Constraints

 \checkmark Additional rules specified by users or database administrators.

Chapter Review Questions

- 1. State the three properties of database relations
- 2. Differentiate between Entity integrity and Referential integrity

Cornolly T. \$Begg C., Database systems: a practical approach to design, implementation and management

CHAPTER FOUR

 \odot

ER-TO- RELATIONAL MAPPING

Learning objectives:

By the end of the chapter a student shall be able to:

 Understand and apply Direct mapping from conceptual model in to relational understand

4.1 ER-to-Relational Mapping

To convert an Entity-Relationship design to a relational database schema, a procedure which includes the following steps may be followed.

WWW.Masomonsingi.com

Types of Entity Conversion

Regular Entity Conversion
 Weak Entity Conversion
 Relationship Conversion

✓ Binary Relationship Conversion

1:1 Relationship Conversion1:Many Relationship ConversionMany:Many Binary Relationship Conversion

✓ Non-Binary Relationship Conversion Attribute Conversion

• Multivalued Attribute Conversion

Regular Entity Conversion

- ✓ A regular entity is implemented as a relation which contains as its attributes all of the attributes of the entity.
- ✓ Any key attribute (or set of attributes) may be used as a candidate key in the relation.
- ✓ All non-atomic attributes are lost. If it is truly desired to retain non-atomic attributes, then alter the ER model so that the compound attribute is an entity.

Consider the student example:

The corresponding relational model would be:

The corresponding relational model would be:

Student			
ID_number	Major	Last Name	First Name

✓ To maintain the existence of the compound attribute Name, re-design the ER schema as follows:

WWW.Masomonsingi.com

 \checkmark Then apply the techniques described for binary relationships.

Weak Entity Conversion

The technique is similar to that for a regular entity conversion, except that the primary key of the owner entity must be included, as a foreign key, in the relation for the weak entity.

Relationship Conversion

For relationship conversion, it is assumed that the entities participating in the relationship have already been converted according to the rules identified above.

One-to-One Binary Relationship Conversion:

www.masomonsingi.com

- \cdot Choose one of the relations (say R1) as the controller.
- \cdot Add the primary key of the controller to the other relation (R2 in this case) as a foreign key.
- · Also add any attributes associated with Rel to R1.
- \cdot Alternative: Merge the two relations into one.(Only appropriate if the individual relations are not needed in other constructions.)
- \cdot If one side is (0,1) and the other (1,1), it is preferable to insert the key from the (0,1) side into the relation of the (1,1) side. This avoids unnecessary use of null values.

One-to-Many Binary Relationship Conversion:

• Insert the primary key K2 of the "1-side" entity as a foreign key into the relation R1 of the "n-side" entity.

 \cdot Also add any attributes associated with Rel to R1.

Many-to-Many Binary Relationship Conversion:

• The new relation S has, as foreign keys, the primary key of each of E1 and E2.

- · Include primary key pairs which "match" in the relationship Relationship
- · Also include any attributes directly associated with Relationship

Non-Binary Relationship Conversion:

• Create a new relation S which contains as attributes each of the primary keys of the participating entities. These will be foreign keys.

· Also include any attributes directly associated with Relationship

Multivalue Attribute Conversion:

WWW.Masomonsingi.com \cdot Create a new relation RA which contains the attribute A, in addition to the primary key of R.

 \cdot There is one tuple for each (Primary Key, Attribute value) pair.

Chapter Review Questions

- 1. Explain the difference between regular and weak entity conversion
- 2. Explain the steps of many-to-many relationship conversion

Cornolly T. \$Begg C., *Database systems: a practical approach to design,* implementation and management

CHAPTER FIVE

 \odot

FUNCTIONAL DEPENDENCIES AND NORMALIZATION

Learning objectives:

By the end of the chapter a student shall be able to:

- ✓ Define partial dependencies and full dependencies
- ✓ Understand transitive dependencies
- ✓ Understand dependency diagram
- ✓ Rules about functional dependency

5.1 Definition of partial dependencies and full dependencies

What is Normalization?

Normalization is a data analysis technique for producing a set of relations with desirable properties

There are three basic levels of normalization: First (FNF), Second (SNF), and Third (TNF) Normal Forms.

It is the TNF that is usually used as the basis for the design of the data model and for mapping onto a database

Advantages of Normalization

- It is a formal technique with each stage of normalization process eliminating a particular type of undesirable dependency
- It highlights constraints and dependencies in the data and hence aids in understanding the nature of data
- The TNF produces well-designed databases which provide a higher degree of independence

Un-normalized Form

A relation that contains one or more repeating groups i.e. repeated values for particular attributes with a single record

First Normal Form

A relation is said to be in FNF if and only it contains no repeating groups Remove repeating groups and propagate higher level primary keys by partitioning the unnormalized relation

Second Normal Form

www.masomomsingi.com A relation is in SNF if and only if it is in FNF and every non-key attribute is fully functionally dependent on the key attribute Remove any partial dependencies by partitioning the relation A relation that is in FNF and has no composite key is necessarily in SNF!

Third Normal Form

A relation is in TNF if and only if it is in SNF and every non-key attribute is independent of all other non-key attributes

Remove any non-key attributes that depend on other non-key dependencies (transitive dependencies)

Functional Dependency

Given a relation R, attribute Y of R is functionally dependent on attribute X of R, if and only if each X-value in R has associated with it precisely one Y-value in R (at any one time) R.X ----- \rightarrow R.Y (R.X functionally determines R.Y)

Normalization Steps

Represent the un-normalized relation List Attributes **Identify Repeating Groups** Identify Key Attributes

Convert to FNF

By removing Repeating Groups Understand the Dependencies Functional Dependency Diagrams may be used

Convert to SNF

by removing partial dependencies

Convert to TNF

by removing transitive dependencies

Rationalize the Results

Consider whether to combine any resulting relations that have identical keys

Discard any relations that is redundant i.e. its attributes are contained within another relation

Identify foreign keys

Review the names of the relations to ensure they reflect the information content

Examples on how to remove dependencies

• Un-normalized Relation

INVOICE InvoiceNo CustomerNo CustomerName Address City Phone Date OrderNo Rep FOB Code Description Qty UnitPrice Total Subtotal Shipping Vat Grandtotal Paymentmode Ccno Ccname Ccexpiry Authorizationcode Normalization Example: FNF INVOICE InvoiceNo CustomerNo CustomerName Address City Phone Date OrderNo Rep FOB Subtotal

Shipping Vat Grandtotal Paymentmode Ccno Ccname Ccexpiry Authorizationcode

PRODUCT

InvoiceNo <u>Code</u> Description Qty UnitPrice Total Normalization Example: SNF • **INVOICE** InvoiceNo CustomerNo CustomerName Address City Phone Date OrderNo Rep FOB Subtotal Shipping Vat Grandtotal Paymentmode Ccno Ccname Ccexpiry Authorizationcode **INVOICE-PRODUCT** InvoiceNo Code Qty Total PRODUCT <u>Code</u> Description UnitPrice

• Normalization Example: TNF **INVOICE InvoiceNo** CustomerNo * Date OrderNo * Rep FOB Subtotal Shipping Vat Grandtotal Paymentmode Ccno * Authorizationcode CUSTOMER **CustomerNo** CustomerName Address City Phone **CREDIT** <u>Ccn</u>o Ccname Ccexpiry **INVOICE-PRODUCT InvoiceNo** Code Qty Total PRODUCT <u>Code</u> Description UnitPrice

Example: An invoice

					cindi.com
Example: Ai	ı invoice				1.masomorns
Invoice No.		D	ate		- nn
Customer		D	elivery to		_
Address					
◀───					
Product Code	Descriptio	n Quantity	Price	Amount	
Than	k you.		Amount_		

Un-normalised data.

Invoice (Invoice no., Date, Customer, Cust_address, Deliv_To, Product code, Quantity, Unit Price, amount, Invoice amount)

INF (Identify and separate repeating groups to form a new entity)

INVOICE (Invoice number, date, customer address, Deliv_ address, Invoice_Amount) **PRODUCT** (Product code, invoice number, product description, Quantity, Unit price, amount)

2NF (identity and separate non-key attributes not fully dependent on key attribute)

INVOICE (Invoice-no, date, customer address, del.address, invoice total) **PRODUCT** (prod-code, prod-description, unit price) **INVOICE PRODUCT** (Prod_Code,Invoice_No,Quantity,Amount)

3NF (Identify non-key attributes dependent on other non-key attributes)

INVOICE (Invoice-no, Customer_Number, Date, invoice total) **PRODUCT** (Prod-code, prod-description, unit price) **INVOICE PRODUCT**(Prod_Code,Invoice_No,Quantity,Amount) CUSTOMER (Customer_Number, Customer_Name, customer_Address, del.address)

www.masomonsingi.com

NB: Whenever there is no composite key the table is in 3NF

Advantages of Normalization Approach

- 1. It is a formal technique with each stage of normalisation process elimination a particular type of undesirable dependency as well as each stage of normalisation eliminating a certain type of redundancy.
- 2. It highlights constraints and dependencies in the data and helps in understanding the nature of the data.
- 3. The 3NF produces well-designed databases, which provide a high degree of independence.

Disadvantages

- 1. It depends a thorough understanding of the entities and their relationships.
- 2. It's a complex process particularly if the entities are many.

Review Questions

1. A customer account details in a bank are stored in a table that has the following structure, normalise this data to 3NF.

www.masomornsingi.com

Customer (branch -no, account no, address, postcode, tel)

- 2. What is transitive dependency?
- **1.** Cornolly T. **\$Begg C.,** *Database systems: a practical approach to design, implementation and management*

Sample Exam Questions

Mt Kenya University UNIVERSITY EXAMINATION 2010/2011

SCHOOL OF APPLIED AND SOCIAL SCIENCES DEPARTMENT OF INFORMATION TECHNOLOGY

BIT 2102 : DATABASE SYSTEMS

TIME: 2HRS

INSTRUCTIONS: SECTION A IS COMPULSORY.ANSWER ANY OTHER TWO QUESTIONS IN SECTION B

SECTION A QUESTION ONE

- a) Define the following terms
 - i. Database
 - ii. DBMS
 - iii. Foreign key
 - iv. Attributes
 - v. Relationship

10marks

WWW.Masomonsingi.com

- b) Explain the three levels of ANSI-SPARC three level architecture 6marks
- c) You are instructed to develop a database system to store the information of patients visiting the given hospital.
 - i. Name six(6) attributes/fields needed for the system 6marks
 - ii. Identify the primary key which can be used to differentiate between the patients. 1mark
- d) Define the term normalization and explain the three normal forms 7marks

SECTION B

QUESTION ONE

a) Based on the following table

Hotel (hotelNo, hotelName, city)

Room (roomNo,hotelNo, type, price)

Booking (HotelNo,GuestNo, DateFrom, DateTo, RoomNo)

Guest(GuestNo, GuestName, GuestAddress)

Where hotel contains hotel details hotelNo is the primary key

www.masomonsingi.com Room contains room details for each hotel and (roomNo, HotelNo) forms the primary key.

and Guest contains Guest details and GuestNo is the primary key.

Write an SQL statement for the following:

- a) List full details of all hotels in London. 5marks
- b) List the names and addresses of all guests in London, alphabetically ordered by name

		5marks
c)	List the price and type of all rooms at the Grosvenor Hotel.	5marks

d) List the number of rooms in each hotel in London 5marks

QUESTION TWO

- a) Describe five advantages of database management system 10marks
- b) Explain the three database languages 6marks
- c) "The File-based Approach had several challenges" explain the statement (4marks)

QUESTION THREE

a) ABC Ltd plans to computerize its sales ordering and stock control system. A feasibility study has strongly suggested that a relational database system be installed. The details of ABC's sales and stock control are as follows:

Customers send in orders for goods. Each order may contain requests for variable quantities of one or more products from ABC's range. ABC keeps a stock file showing for each product the product details and the preferred supplier, the quantity in stock, the reorder level and other details. ABC delivers those goods that it has in stock in response to the customer order and an invoice is produced for the despatched items. Any items that were not in stock are placed on a back order list and these items are usually re-ordered from the preferred supplier. Occasionally items are ordered from alternative sources. In response to the invoices that are sent out to ABC's customers, the customers send in payments. Sometimes a payment will be for one invoice, sometimes for part of an invoice and sometimes for several invoices and part-invoices.

Draw an entity-relationship model, stating any assumptions made. 10marks

WWW.Masomonsingi.com

- b) Differentiate between the following
 - i. Super-classes & Subclasses
 - ii. Primary key and foreign key
 - iii. Recursive Relationship and Inheritance
 - iv.Weak Entity and entity

10marks

QUESTION FOUR

a) Consider the following relation:
OrderItem (OrderNo, ItemCode, Quantity, OrderDate, Description, CustomerNo, CreditLimit, DeliveryAddress)
The following Functional Dependencies (FDs) apply to OrderItem:
FD1 OrderNo, ItemCode -> Quantity
FD2 OrderNo, ItemCode -> OrderDate
FD3 ItemCode -> Description
FD4 OrderNo -> CustomerNo
FD5 CustomerNo -> CreditLimit
FD6 CustomerNo -> DeliveryAddress
(i) Define the two Transitive Dependencies that can be derived from the FDs and give an explanation of the derivation.

(4 marks)

(ii) (ii) Given the FDs above, normalise the OrderItem to 3NF, carefully showing your intermediate steps.

(8 marks)

b) Employees table

	Title	FirstName	LastName
1	Inside Sales Coordinator	Laura	Callahan
2	Sales Manager	Steven	Buchanan
3	Sales Representative	Nancy	Davolio
4	Sales Representative	Anne	Dodsworth
5	Sales Representative	Robert	King
6	Sales Representative	Janet	Leverling
7	Sales Representative	Margaret	Peacock
8	Sales Representative	Michael	Suyama
9	Vice President, Sales	Andrew	Fuller

Write SQL statements do the following

i. Retrieve all columns in the employee table 2 marks

ii. List all the sales representatives

iii. List the firstname and last name of employees 3marks

3marks

SCHOOL OF PURE & APPLIED SCIENCES IT DEPARTMENT

BIT 2102: DATABASE SYSTEMS

2 HOURS

INSTRUCTIONS

- Answer all questions in section A and other <u>TWO</u> in section B
- > No reference material allowed
- > Time <u>2</u> Hours

SECTION A (COMPULSORY – 30 MARKS)

QUESTION ONE

- a) Define the following terms.
 - a) database
 - b) database management system
 - c) data integrity
 - d) schema
 - e) instance

[10mks]

ii) Discuss the business conditions that enable a business database to be effective.

[10mks]

iii) a) distinguish between a logical and physical data independence. [4mks] b) Explain the purposes of the three DBMS languages [6mks]

SECTION B

QUESTION ONE

2 a) Consider the table structure below.

TABLE STUDENT:

STUDNO	LNAME	FNAME	INITIAL	DOB	UNIT CODE

					on
					MSIL
	1	1	l		
101	Mwangi	John	Ν	11/8/80	2100
102	Kimaiyo	Peter	М	12/12/84	2200
103	Chebet	Martha	К	2/4/83	2305 1
104	Oduor	Louis	М	11/06/80	2200
105	Njuguna	Frank	G	15/9/85	2100

Using SQL,

	i. ii.	Create the table STUDENT Having created the table structure in (i) above, enter t	[3 Mks] he first two
	iii.	Return the names of students taking unit code 9945	[2 Mks]
	iv.	Remove the table STUDENT from the database	[2 Mks]
b)	v.	Order the table by unit code in ascending Hence explain the usage of these clauses: JOIN and CALCU	[2 Mks] ILATE
			[4 Mks]
c)		Describe the following terms.	[5mks]
		i) entity	
		j) attribute	
		k) relationship	

QUESTION TWO

a)	Identi	es of distribution	
			[12 Mks]
	b)	What do you understand by E-R Modeling?	[2 Mks]
		Hence explain briefly terms:	[6 Mks]
	i.	Cardinality	

- ii. Composite attribute
- iii. Weak attribute

QUESTION THREE

a) with the aid of well labeled diagrams describe the three types of relationships.

		[12mks]
b) Distinguish b	etween generalization and specialization.	[4mks]
c) Explain t	he roles of a database administrator	[5mks]

QUESTION FOUR

a) Explain the term normalization. and hence Outline the nature of the following

normal forms

i) 1st normal form

ii) 2nd normal form

iii) 3rd normal form

- b) Explain five roles of a data base administrator.
- c) Discuss the properties of a transaction.

[3mks] [10mks)^{WW.Masomonsindi.com} [10mks]
